Wow, you're answering fast. Ok, of course I did the same analyses with the TPC. The track reconstruction efficiency is better like you said. It goes up to 90%, but especially in the low momentum range you can see the same behavior.

MVD+TPC+GEM, standard macros in tutorial folder

The blue criterion means that no track is produced. Very low momentum pions decay before a detector is reached and as a result to less points (<3 MVD+TPC hits) are created for tracking. So this is should be just a physical reason.

greetings,
David
