Dear all,

Laura has fixed the calculation of the reconstructed dE/dx in PndPidCorrelator class. You can try to run macro/pid macros and to plot the dE/dx from PidCandidate.

If I shoot the detector with 1GeV/c muons, I have the following dE/dx distribution:

(unity: GeV/cm).

Just fitting the distribution with a landau (as it should be), we obtain the following values:

MPV: 2.83 MeV/cm

sig: 0.23 MeV/cm

If we consider the silicon density $\rho = 2.33 \text{ g/cm}^3$

-> dE/dx ~ 1.21 [MeV cm² / g]

I would like to ask to MVD experts how much is the "theoretical value", I would suppose you have already some tables with the correct values.

We have also compared the reconstructed dE/dx with the MonteCarlo value, and the results seem in agreement, but I would like to know what is coming from "physics" before believing blindly in simulation.

Thanks in advance.
