Hello Stefano,

positive semi definite does not mean that there cannot be negative values.

The Definition says, that any vector y multiplied in the way: $y^t * C * y$,
where C is the Covariance Matrix, must result in a value greater or equal to zero.

In a way that is the proof, that the Chi-Square value ($y^t * C^{-1} * y$) is always positive.

Or rather, if C is not positive semi definite, then it cannot be guaranteed that the Chi Square value is positive.

It is a mathematical property that every Covariance Matrix Must have.

Cheers
Simon
