Hi Alberto,

that is right: if the strict-merge option is active, an event is only analyzed if both, AGATA and MBS data are present.

What data is present is determined during the merging procedure: the lowest GTS timestamp opens a time window (default is 3us can be adjusted with the --replay-merge-time-window= option). If any other data set comes within this time window, it is put into the event. Typically, a MBS event comes first (opens the time window), followed by one or more AGATA events (PSA-frames).

Best regards,
Michael
