---

Hi all,

I have a problem with the "standard" sim macro.

I run a test simulation for  $p\bar{p} \rightarrow \Xi(1820)^+ \Xi^-$  with 1000 events and a beam momentum of 4.6 GeV/c .

When I look into the macro output `sim_complete.root` there are two `cbmsim` branches named `cbmsim;1` and `cbmsim;2`. The number of entries in `cbmsim;1` is smaller than in `cbmsim;2`. And the number of generated particles with `motherID==1` is not matching for `cbmsim;1`. (For `cbmsim;2` everything seems to be fine.)

The problem is that the standard pid macro seems to use `cbmsim;1`.

If I reduce the number of events to e.g. 500, there is only one `cbmsim` branch with the correct number of generated particles in the output file.

Can anyone help me with this problem?

I attached the sim macro, my .dec-file and a modified `evt.pdl` which contains the added  $\Xi(1820)^+$  particle.

Cheers  
Jenny

-----  
I'm using:

PandaRoot: trunk rev. 28555  
Fairsoft: mar15  
FairRoot: master
