Did someone observe a distinct task using lots of CPU power?
Some optimization might be possible.

I would agree that online runs could go with less precision, i.e. neglect small corrections etc.

Did someone try march-native on the gsi machines?

Maybe try to enable link-time optimisation, fast-math, profile-guided optimizations, and/or rename-registers?

Some speed might be gained there, but this will of course not help if the bottleneck is the network's bandwidth.
