Stefano Spataro wrote on Mon, 27 August 2007 13:08Hi,
trying to find some clue...

I can see that you are using the CbmG4.so library, why? You should comment out this include,
if you have it. It is only when one want to use particolar physics lists. This library is not used at
the moment, and gives problems.

I use it because nobody told me that I shouldn't do this.   Ok, I will comment it out.

Quote:
And second, did you change the g4Config.C file? It seems you activated the hadronic lists. It
could be that there are some differencies in G4 so that the virtualMC is not able to handle
particular cases.

No, I didn't touch g4Config.C.

Quote:
In each case it seems that all the errors you ahve are not dependent from the pandaroot
release (apart the g4Config.C), so I am wondering why it does not prodice the same crashes in
the main svn version...

Yes it looks like that, but how you can explain the fact that exactly the same external
packages are working with the head version without error?

Best regards,

        Andrey
