Subject: Conversion of track parameters

Hello,

let's assume that I have one track represented by a parabola (FairTrackParP), and I want to convert it into a helix (FairTrackParH). What should I do exactly?

I have seen there is a class FairGeaneUtil doing conversions, but it is not using FairTrackPar objects, and for me SC SD Pt MARS are just understandable acronyms.

Is there some function doing the conversion in a simple way?
