
Subject: Disagreement between the LISE++ calculations and the experiment

Dear All,

We found a disagreement on the production ratio of the fragments after the secondary target, between the LISE++ simulations and the experimental data.

I have written an informal and small report to explain a little bit the situation, please find it in the attachment. It would be appreciated if somebody experienced on this setup share his/her knowledge and comment on the report.

Thank you very much!

Tayfun

Thanks to Magda and Giulia who reminded us using the triggers.

So this was as simple as the trigger conditions. I was using all triggers, and particles with higher multiplicity gammas enhanced in E vs dE plot.

Using only Trigger 10 makes results coherent with the simulations.
