Dear trackers,

I'm trying to make the tracking with DCH, GEM and MvD detectors in Forward spectrometer.

I found a tracking tools with DCH, it works very fine.

And GEM with 4 stations are partly implemented and doesn't nicely response in all momentum range.

MvD can use in principle, but it is not combined with other(GEM, DCH) detectors.

I realize that there is still no global tracking with MvD+DCH+GEM.

But I expect some kind of combined DCH+MvD or DCH+Gem tools are available to use if someone already working for Forward spectrometer part.

Could you make some comment and give me useful informations about FS tracking?

Best wishes,
Donghee Kang

Hi,
in the region of the forward angles, for the moment, there is no global tracking. You can use dch stand alone, maybe mvd or gem standalone, but you do not have correlated information.

Hi,

what do you mean with 'there is no global tracking for MVD, GEM & DCH'? It is in principle true, but all these groups use genfit. So to combine these into one global tracking is only an organizational problem, not a technical one.

Donghee: Are you maybe interested in trying this task? I guess that is all the 3 experts from the detector groups show you their macros, it shouldnt be a big problem. You would have to modify the recotasks/KalmanTask.cxx very slightly to contain hit producers for the three detectors. A hit producer is code which does for example:

for detector id 6, I take the following TClonesArray of reconstructed clusters and for each one I call the ctor SomeRecoHit(SomeCluster*).

Then you would need a pattern recognition which makes one TrackCand object containing all clusters from the 3 detectors, which should be possible by combining all the three pattern recognitions together (this would be in something like ForwardGlobalPatternRecoTask or so). In this task you would set up the Track objects which are then fit in the KalmanTask.

If you would like to try this, I could tell you a little more with the TPC example, how it is done.

Cheers, Christian

Dear stepano,

In principle, I have now two different options.

I can try to implement FS tracking with at least 3 detector components MvD+Gem+Dch. LHE tracking should very useful reference to do that.

To perform this, I have to rearrange following files.

I guess that I need quite lots of time(no time estimation!) and to care and learn many fit algorithms.

Quote:

PndLheContFact.cxx
PndLheCorrPar.cxx
PndLheHit.cxx
PndLheHitsMaker.cxx
PndLheKalmanTask.cxx
PndLhePidMaker.cxx
PndLhePidTrack.cxx
PndLheTpcPlanarRecoHit.cxx
PndLheTrackFinderIdeal.cxx
PndTpcLheCMPoint.cxx
PndTpcLheCMTrack.cxx
PndTpcLhePoint.cxx
PndTpcLheSegments.cxx
PndTpcLheTrackCuts.cxx
PndTpcLheTrack.cxx
PndTpcLheTrackFinder.cxx
PndTpcLheTrackFitter.cxx

A patient waiting is another option.

In this case, I can study individual detector performance a bit more in detail.

I want to know how long do I have to wait, roughly?

Could you give some comment what the situation is?

Best regards,
Donghee

Hi,

it is not quite true that there is nothing concerning forward tracking. Recently Radek tried (with a little bit of my help) to merge information from gem and dch. The results of our efforts you can find in the fwd directory and the corresponding macro/fwd directory.
It is very simple for the time being, using MCtruth info in quite many places of the code, but still IT DOES NOT WORK as expected. Moreover, even if one switches off one of the detectors, e.g. gems, one would expect to reproduce results obtained in the "stand-alone" detector's code, e.g. in the dch macros. Unfortunately, it is not the case, so most likely there is still a problem somewhere in this code, which needs more careful debugging. Nevertheless, it is a good starting point for further development. Feel invited to do that.

regards,
ola

Dear Christian,

That is surely great idea!
I would be really happy, if I can join this subject and if there are no other argument. I will try to give some small contribution for the forward spectrometer tracking.

I would like to discuss dch and gem standalone tracking.
If I look and run dch tracking macro, i have very reasonable spectra. you can also find dch_mom.eps _theta.eps _resolution.eps and xyview.eps, that are defined by dch tracking.
Blue one is reconstruced from dch tracking, red for generated one in one dimension plot.
x and y units in 2D plot are [m] meter.

But if I have tested gem alone, the result is changing dramatically. I have a look all hits information, which is prepared in GEM macro, most of hits are dedicated near the 0.5cm radius in 4 station GEM, however identified tracking in GEM are located far way at roughly 50cm. As well as reconstruction efficiency are quite bad.
Roughly 20% events are only reconstruced in GEM stations.
I think that GEM has some problem in the tracking.

Could you confirm this?

Best wishes,
Donghee Kang from Mainz

Dear Donghee!

I cannot but agree that the tracking in the forward detector of GEM is not yet working as I would like it to work. I have few problems however with your study.

You have presented a theta and momentum distributions of the protons that you use in your analysis. I assume that the momentum distribution is in GeV/c and then it looks a bit strange, why do you have so energetic particles? The curvature for those in the barrel magnet is extremally small and thus momentum identification rather difficult.

The bigger concern I have to the theta distribution. I assume the theta is in degrees, which means that you have generated very forward going particles (which makes momentum determination even more difficult) but what is more important, the lower GEM detector acceptance is about 3.5 degrees!!! which means all your protons went through the inner hole of the GEM detector. Then your inefficiency is very simple to explain. You can't have tracks if you don't have points.

Could you therefore please show me the GEM point distribution and the number of GEM points on different stations?

For example open your MC file in root and execute:

```
cbmsim->Draw("GEMPoint.fY:GEMPoint.fX","GEMPoint.fZ<89.6")
```

This should give you the number of points on the first GEM station. You could also check the next stations, but if this number of point per station is significantly smaller than 10000 (which is the number of your protons), then forget about reconstruction in GEM.

Sincerely yours,
radek

ps. sorry for late answer

Dear Radek,

Thank you for your kind looking of my plots.

You are perfectly right in some point!

I agree that GEM acceptance is quite limited and difficult to use in my task.

Therefore we need helping of MvD and DCH.

You can now find some hit information and kinematic plots at GEM stations.
Gem_4stations.eps is the hit distribution, prepared originally in the GEM Macro.
Gem_xyview_zoom.eps is 2D hit information in x-y plane.
Gem_rzview.eps is the hit information in z-direction.
gem_mom.eps gem_theta.eps are the comparison with generated one.
ggem_resolution.eps is the corresponding resolution plot in 2D level.
Y-axis is the (mom_generated - mom_reconstructed) in the left panel
and the (theta_gen - theta_reco) for right panel.

If you see gem_theta.eps, the acceptance is over 2.2 degrees.
However if I have a look the resolution for momentum and theta.
All resolutions are really bad even if GEM succeed proton tracking for relatively large angle!

I'm wondering why GEM cannot make reasonable tracking with good resolution, when proton has large angle!
GEM stations should be fired in 4 stations. That means they have already 4 hits, and I think that is enough information to try reconstruction.
Is it still not enough hits to perform that? This is my real question!

Thank you!
Donghee Kang

[View Forum Message](#) <> [Reply to Message](#)

Dear Radek, Aleksandrma

I'm trying to give a contribution for the tracking of forward spectrometer.
My task would be simple and a combining of mvd+gem+dch detectors as you can imagine.
As a first step, I made a copy of your nice macro in the pandaroot macro/fwd
/PndFwdPrepareKalmanTracks.cxx and /PndFwdKalmanTracks.cxx

I have a small question for the usage of the function RecoHitFactory::addProducer(detID, *hitProd)
To put certain hit producer module in this hit register, one needs to define or know detector ID.
If I have a look for example GEM and DCH case, kGEM and kDCH can be found.
Are these values kGEM and kDCH integers? Where are they initialized?
I couldn't read kGEM and kDCH in both PndFwdKalmanTracks.cxx and

PndFwdPrepareKalmanTracks.cxx, also in each header they are not defined if I have checked correctly.

Quote:

```
fTheRecoHitFactory->addProducer(kGEM,new  
RecoHitProducer<PndGemHit,PndGemRecoHit>(gemHitArray));
```

Second question is the conceptional design of PndFwdPrepareKalmanTracks::Exec().
If I put mvd detector, the iteration must be starting from mvd, how do you think?

Quote:

```
std::cout << "Looping over " << nofGemTracks << " gem tracks" << endl;  
for (Int_t igemtr=0; igemtr<nofGemTracks; igemtr++){
```

My last question is for the understanding of PndPrepareKalmanTracks code.

This code prepare a pattern recognition with many hits.

The preparation has been started with GEM tracks, and then looking DCH tracks.

At the end all hit(in GEM and DCH) distributions are used to build a track.

If I want to use MVD, then do I have to make Mvd track also? because GEM and DCH has some

kind of tracking container in this stage.

or Do you think that I can use MVD hit without MVD track container during preparation?

Do you have some idea?

Thank you for your time!

Donghee Kang

[View Forum Message](#) <> [Reply to Message](#)

Dear Donghee,

First of all, the kMVD, kGEM, kDCH are defined in /trunk/pnddata/PndDetectorList.h.

As for the addition of the MVD, I think that both for GEM and DCH, the PrepareKalmanTracks tasks are taking the existing detector local tracks and build the Tracks that are understood and worked on by the KalmanTask itself. We have decided to make the

PndFwdPrepareKalmanTracks accordingly, so that it takes GEM and DCH local tracks and combines them into Tracks. For now the task is very bad designed, I have to admit it (I created this, Aleksandra would have made a better job), because it works only with the MC information available. In future implementations it should be changed, have to be changed, and probably

the task of merging GEM and DCH tracks together should go into other task.

As for the second question, the iteration can start from MVD at the moment, but I think we have to agree on this later on. In fact I would think that merging the tracks between different detectors should start from a detector with smallest amount of tracks/smallest acceptance (I did not think a long time about the problem, just guestimating).

Last answer is that PrepareKalmanTracks is working on tracks, not on hits. So it combines (at the moment, see previous remarks) tracks from different detectors, and the hits are there only to be placed in the resulting Track object.

Hope that answers your questions
radek

Hi Donghee,

I want to stress again, that the GEM fitting is not performing as I would like it to do. My next forum response will be about it. I am not such a good forum participant as you are;).

I would like to ask you, if you do the reconstruction in GEM alone, or in GEM/DCH together?

As for the fitting results: it is the combination of the number of points you have for the reconstruction and the track curvature. I agree for higher theta angles the resolution should be better, but see the first sentence of the message.

Before replying, wait for my message to the GEM tracking...

yours,
radek

[View Forum Message](#) <> [Reply to Message](#)

Dear Radek,

When I study on the FS tracking, the reconstruction have been done GEM and DCH alone, separately.

I can well understand what we have to do, what we need to do in the future.

Please don't be stress. I always thank you for your great efforts, specially GEM tracking and combined forward tracking.

If I don't have this kind of useful helps, I cannot succeed all study in time, forever.
I will wait good news on the GEM.
I think that it is also great to discuss ideas with you, continueously.

Have a good day!
Donghee Kang

[View Forum Message](#) <> [Reply to Message](#)

Dear Christian,

Thank you for your kind teaching. I have few question to work the FS tracking, efficiently.
I have few references, but every suggestions indicate slightly different way. That is a bit confusing!
If I have some misconception, please correct me!

Quote:

1. You would have to modify the recotasks/KalmanTask.cxx very slightly to contain hit producers for the three detectors.
2. take the following TClonesArray of reconstructed clusters and for each one I call the ctor SomeRecoHit(SomeCluster*).
3. a pattern recognition which makes one TrackCand object containing all clusters from the 3 detectors
4. If you would like to try this, I could tell you a little more with the TPC example, how it is done.

Concerning your comment 1:

Actually, we don't need to use MVDPoint, PndDchPoint and GEMPoint class, which are produced in simulation file for the fitting purpose. Is it correct?

Thus, I'm going to use hit containers in the digi file.

GEMHit, MVDHitPixel, MVDHitsStrip and PndDchCylinderHit classes are probably important to use three detectors.

Concerning your comment 2 & 3.

DemoPatternRecoTask or PndDchPrepareKalmanTracks has roughly same structure.

I assume that these two file has only different name, but they have same purpose.

They make a track candidate from local track including local detector hits!

This procedure can be called a pattern recognition, is it right?

After this setp, we have now quasi-reconstructed track(candidate) and quasi-reconstructed hit(according quasi-reconstructed track).

Finally, in the Kalmantask, the actual fitting can be performed for all quasi-reconstructed track candidate and find real reconstructed track candidate when the kalma fits are finished successfully.

I have one trouble to make clear understanding.

I thought that a pattern recognition simply can be made only with hit information as suggested in DemoPatternRecoTask.

But for example, PndDchPrepareKalman prefer to use local track, which is defined with one detector component in digi procedure.

I expect that it doesn't matter what we use, because local track have some hit information in any case. This is only different approach, is it correct?

Concerning your comment 4.

Where is it? Could you show me that?

Thank you for your time!

Cheers, donghee
